## Rule WLM122: Significant transaction time was in Idle state

## Finding:

A significant amount of the transaction response time for the service class missing its performance goal was spent in the Idle state. This finding applies to service classes which are part of a subsystem (e.g., CICS transactions).

## Impact:

This finding has NO IMPACT, LOW IMPACT, MEDIUM IMPACT or HIGH IMPACT on performance of the service class. The finding primarily indicates that either (1) the workload classification scheme improperly groups conversational transactions in the same service class as nonconversational transactions or (2) the performance goal has been improperly specified for the service class.

Logic flow: The following rules cause this rule to be invoked:

> Rule WLM104: Subsystem Service Class did not achieve average

> > response goal

Rule WLM105: Subsystem Service Class did not achieve percentile

response goal

**Discussion:** When CPExpert produces Rule WLM104 or Rule WLM105 to indicate that a subsystem service class did not achieve its performance goal, the logic of these rules tries to identify the cause of the delay. The cause of the delay initially is analyzed from the "served" service class view. The delays from the served service class are reported by CICS/ESA Version 4.1 or IMS Version 5 interaction with the Workload Manager, using the Workload Management Services macros<sup>1</sup>.

> CICS/ESA Version 4.1 reports two separate views of the transactions: the begin\_to\_end phase and the execution phase<sup>2</sup>.

> • Begin\_to\_end phase. The begin\_to\_end phase starts when CICS/ESA Version 4.1 has classified the transaction<sup>3</sup>. This action normally is done in a CICS Terminal Owning Region (TOR).

<sup>&</sup>lt;sup>1</sup>Please refer to Section 4 of this document for more detail about the Workload Management Services macros and how the subsystems use these macros to exchange information with the Workload Manager.

<sup>&</sup>lt;sup>2</sup>IMS Version 5 reports only *execution phase* samples.

<sup>&</sup>lt;sup>3</sup>Classifying the transaction into a service class is actually done by the Workload Manager when CICS issues the IWMCLSFY macro. Please refer to Section 4 for a more complete discussion of the subsystem work manager (e.g., CICS) interaction with the Workload Manager.

 Execution phase. The execution phase starts when either CICS/ESA Version 4.1 or IMS Version 5 has started an application task to process the transaction. For CICS, this normally is done in a CICS Application Owning Region (AOR).

Within each phase, CICS or IMS reports the "state" of the transaction, from the view of CICS or IMS. The state of the transaction is reported in the following categories<sup>4</sup>:

- Idle state.
- Active state.
- · Ready state.
- Wait state.
- Switched state.

If the subsystem supports work manager delay reporting, the delay information is available in the "Work Manager/Resource Manger State Section" of SMF Type 72 (Subtype 3) records. When a transaction service class fails to achieve its performance goal, CPExpert analyzes the information to identify the primary and secondary causes of delay.

CPExpert produces Rule WLM122 when the primary or secondary cause of delay was that the transaction service class was in the Idle state for a significant percent of its response time. The Idle state indicates that no work request was available to the work manager (CICS or IMS) that is allowed to run.

For CICS transactions, this is the time accounted for by tasks executing in the CICS region. These tasks would be shown as "Suspended" by the CEMT INQUIRE TASK command.

For CICS transactions, this time differs depending upon the types of tasks executing.

- Tasks could be waiting of a principal facility (for example, conversational tasks which were waiting for a resource from a terminal user).
- The Terminal Control (TC) task (CSTP) could be waiting for work.

Revised: October, 2001 Rule WLM122,2

<sup>&</sup>lt;sup>4</sup>Please refer to Section 4 of this document for a more comprehensive discussion of the transaction states and the interaction between the subsystem (CICS or IMS) and the Workload Manager.

- The interregion controller task (CSNC) could be waiting for transaction routing requests.
- CICS system tasks (such as CSSY) could be waiting for work.

None of these tasks should be in a service class with a response goal, as neither CICS nor the Workload Manager can provide resources to reduce the response time.

The following example illustrates the output from Rule WLM122:

RULE WLM122: SIGNIFICANT TRANSACTION TIME WAS IN IDLE STATE

A significant amount of the transaction response time for CICUSRA Service Class was spent in the Idle State. For CICS transactions, this time differs depending upon the types of tasks executing.

- Tasks could be waiting of a principal facility (for example, conversational tasks which were waiting for a resource from a terminal user).
- The Terminal Control (TC) task (CSTP) could be waiting for work.
- The interregion controller task (CSNC) could be waiting for transaction routing requests.

- CICS system tasks (such as CSSY) could be waiting for work. These tasks would be shown as "Suspended" by the CEMT INQUIRE TASK command. CPExpert suggests that these transactions be identified and placed into their own service class. Idle time normally should not included in a service class with response performance objectives.

Suggestion: CPExpert suggests that you consider the following alternatives:

Modify your workload classification scheme. The most likely problem
is that the workload classification scheme does not adequately partition
the transactions into time-critical service classes and service classes
which do not have a critical response goal.

CPExpert suggests that you modify the workload classification scheme such that the transactions experiencing Idle state time are placed into a service class different from the service class containing important transactions. While it may be true that the transactions experiencing Idle state time are "important" transactions, the Workload Manager cannot allocate resources to reduce response for transactions which are Idle state for reasons outside the Workload Manager's control.

Review the performance goal for the service class. From a
"conceptual" view, the transactions experiencing Idle state "should" be
assigned an execution velocity goal; they would receive CPU time when
they wanted the CPU time. Unfortunately, the Workload Manager cannot

assign resources to transactions, but assigns the resources to address spaces supporting the transactions. Thus, the Workload Manager ISPF application does not allow transaction subsystem service classes to be defined with any goal other than a response goal.

If you specify a short response goal, the Workload Manager will incur overhead attempting to meet a performance goal for events outside its control. While the Workload Manager often will detect this situation (that is, it will detect that it cannot take action to improve response for the service class), there is no point in having the Workload Manager incur the overhead required to make the decision.

CPExpert suggests that you specify a **very long** response goal<sup>5</sup> for the service class containing the transactions in Idle state. These transactions are idle (Suspended) waiting for events outside the Workload Manager's control.

This action should be done only after important transactions with valid response goals have been removed from the service class! You should modify your workload classification scheme, if necessary, to make sure that the important transactions have been removed from the service class with the long response goal.

<sup>&</sup>lt;sup>5</sup>CPExpert identifies transaction subsystem service classes and will suppress Rule WLM006 for these service classes.
